DECLARATION

I certify that

(a) The work contained in this report has been done by me under the guidance of my supervisor.

(b) The work has not been submitted to any other Institute for any degree or diploma.

(c) I have conformed to the norms and guidelines given in the Ethical Code of Conduct of the Institute.

(d) Whenever I have used materials (data, theoretical analysis, figures, and text) from other sources, I have given due credit to them by citing them in the text of the thesis and giving their details in the references. Further, I have taken permission from the copyright owners of the sources, whenever necessary.

Date: April,2025 (Telu Sai Srinivasa Naidu, Amme Manoj, Kommeta Vikas)

Abstract

Name of the student: **Telu Sai Srinivasa Naidu, Amme Manoj, Kommeta Vikas**

Roll No: **21036159, 21036112, 21036129**

Degree for which submitted: **Bachelor of Technology**

Department: **Department of Information Technology**

Thesis title: **SELF DRIVING CAR- AI AND NEURAL NETWORK**

Thesis supervisor: **Dr. Amit Dewangan**

Month and year of thesis submission: **April, 2025**

The advancement of autonomous driving technology is bringing a new wave of transformation, connecting people and places while reducing dependence on human-driven vehicles. However, developing a fully autonomous car that can drive itself in varied and dynamic environments presents several challenges. Traditional approaches rely heavily on predefined rules and rigid programming, which limit the system's ability to adapt to new situations. Autonomous driving systems must not only detect and interpret sensory data in real-time but also make complex decisions that account for safety, efficiency, and adaptability. To address these challenges, this project explores the NeuroEvolution of Augmenting Topologies (NEAT) algorithm, a genetic algorithm that evolves artificial neural networks. Unlike conventional neural networks with fixed structures, NEAT adapts its structure and weight connections based on a fitness function, creating an ever-evolving and increasingly capable driving model.

NEAT allows the car to "learn" driving skills through successive generations, using a fitness score based on distance traveled and collision avoidance.

Over time, the car improves its navigation skills and decision-making, becoming more adept at handling a variety of driving scenarios.By enabling real-time decision-making, NEAT acts as a bridge between theoretical models and practical application, showing how AI can be harnessed to solve complex driving problems. Through this project, we aim to develop a self-driving car that not only navigates autonomously but also evolves and improves without direct human intervention. This research demonstrates the potential of adaptive, learning-based driving systems to make transportation safer and more accessible, paving the way for a future where AI-driven vehicles enhance everyday life, red accidents, and connect people with greater ease.

Acknowledgements

We, the undersigned, feel immense pleasure in expressing our profound sense of gratitude to our thesis supervisors, Dr. AMIT DEWANGAN , under whose supervision and inspiring guidance, we had the privilege to carry out our research work. We are indebted to them for their constant and ungrudging encouragement, valuable suggestions, and ingenious ideas.

We express our sincere thanks to Dr. AMIT DEWANGAN (Assistant professor), Department of Information Technology and Engineering, Guru Ghasidas Vishwavidyalaya, Koni, Bilaspur, Chhattisgarh, for his support and guidance throughout our project.

We also extend our gratitude to our parents for their unwavering support and motivation throughout this work. Without their encouragement, it might not have been possible for us to complete this study. The blessings of our beloved parents helped us reach this milestone.

Finally, we thank our friends and colleagues for their valuable advice, continued support, and teamwork that made this project a success.

Chapter 1

Introduction

1.1 Introduction

Self-driving cars, also known as autonomous vehicles (AVs), are vehicles that can operate without human intervention by using a combination of sensors, machine learning algorithms, and sophisticated computing systems. These cars are designed to perceive their environment, make decisions, and navigate safely to their destinations without the need for a driver. The development of self-driving cars is a significant breakthrough in transportation technology, driven by advancements in sensors, artificial intelligence (AI), machine learning, and computer vision.

FIGURE 1.1: Example of Self-Driving Car

1.1.1 Importance of Self-Driving Cars

Self-driving cars, powered by AI and advanced sensor technology, have the potential to reshape the transportation landscape by improving safety, efficiency, and accessibility. They can respond to real-time data, reducing human error, which is the leading cause of road accidents, and can adjust driving patterns to optimize fuel use and reduce congestion. With further advancements, autonomous vehicles could create more accessible transportation options, especially for individuals unable to drive. These benefits extend to economic gains, including lower accident and fuel costs, as well as environmental sustainability by reducing emissions.

- **Enhanced Safety**: Self-driving cars minimize human error, which accounts for most road accidents, making roads safer for everyone.
- **Improved Traffic Efficiency**: Autonomous vehicles communicate and coordinate better than human drivers, which can reduce traffic congestion, optimize travel routes, and decrease overall travel time.
- **Environmental Benefits**: Autonomous cars can maximize fuel efficiency and reduce emissions by maintaining optimal driving speeds and smoother routes, contributing to a smaller carbon footprint.
- **Increased Accessibility**: Self-driving cars offer mobility solutions for those unable to drive, such as the elderly, people with disabilities, and individuals without a driver's license.
- **Economic Savings**: Lower accident rates lead to reduced insurance costs, fewer road repairs, and decreased fuel expenses, saving money for individuals and governments alike.

1.2 Project Overview

1.2.1 Objective

The objective of this project is to train a Convolutional Neural Network (CNN) to map raw pixel data from a camera directly to vehicle steering commands for autonomous driving.

1.2.2 Approach

- **End-to-End Learning**: Unlike traditional modular approaches (such as lane detection, path planning, and control), the system learns the entire driving process using minimal human-provided training signals (only steering angles).
- **CNN-Based**: The CNN learns to recognize necessary features like road outlines, lane boundaries, and objects from raw images, eliminating the need for explicit feature engineering or rule-based systems.
- **Real-Time Operation**: The system operates at 30 frames per second (FPS) using NVIDIA DRIVE™PX self-driving car computer, powered by Torch 7 for training and inference.

1.3 Key Benefits

- **No Need for Human-Designed Features**: The system learns to detect useful features autonomously, reducing reliance on explicitly labeled road features (like lane markings or guardrails).
- **End-to-End Optimization**: By optimizing all components simultaneously, the system improves overall performance and efficiency, without human-selected intermediate criteria that may limit performance.
- **Smaller and More Efficient Systems**: Trains the model to solve the problem with minimal processing steps, resulting in smaller, more efficient models.

1.4 Training Data

Data was collected from a variety of environments, including residential, highway, and unpaved roads, in diverse weather conditions (sunny, foggy, rainy, etc.).

1.4.1 Vehicle Setup

Training was conducted using vehicles like a 2016 Lincoln MKZ and a 2013 Ford Focus equipped with cameras and a drive-by-wire system for capturing steering commands.

1.4.2 Data Augmentation

Data was augmented by adding artificial shifts and rotations to the images, helping the model generalize and recover from poor positions.

1.5 Network Architecture

- **9 Layers**: The network consists of 5 convolutional layers for feature extraction and 3 fully connected layers for steering control.
- **Convolutional Layers**: Utilize strided and non-strided convolutions to extract road features and enable efficient learning.

1.6 Training and Evaluation

- The model was trained using supervised learning with labeled data from human drivers and augmented data.
- The performance was assessed by comparing the network's predicted steering commands to the actual commands provided by human drivers, minimizing the mean squared error.

1.7 Results

- The system demonstrated the ability to drive autonomously in varied environments, including traffic, unmarked roads, parking lots, and highways.
- The end-to-end learning system outperformed traditional methods by allowing for a self-optimizing approach that simultaneously improved road feature recognition and vehicle control.

1.8 Technological Foundations

1.8.1 NVIDIA DevBox & Torch 7

The model was trained on NVIDIA's powerful DevBox, and the inference was done using NVIDIA DRIVE™PX, which provided real-time driving capabilities.

1.8.2 System Performance

Achieved 30 FPS, suitable for real-time vehicle navigation.

1.9 Conclusion

This project exemplifies the potential of end-to-end learning for self-driving cars, offering improvements in system efficiency and robustness by leveraging advanced neural networks and large-scale data.

Chapter 2

Methodology

2.1 Implementation of Project

2.1.1 Implementation of Project in 2D

Self-driving car development has been a subject of study for many years. The way we commute could be completely changed by autonomous vehicles, which could also help with traffic congestion and increase road safety.

2.1.1.1 What is NEAT?

NeuroEvolution of Augmenting Topologies (NEAT) is a genetic algorithm (GA) for the generation of evolving artificial neural networks (a neuroevolution technique) developed by Kenneth Stanley and Risto Miikkulainen in 2002 while at The University of Texas at Austin. NEAT is a machine learning technique that evolves neural networks to perform a specific task. The self-driving car simulation is designed to learn from its experiences, adapt to new environments, and improve its performance over time. The simulation environment is created using Unity, a popular game engine, and the car is equipped with sensors that detect obstacles and other cars on the road. The NEAT algorithm evolves the neural network's structure and weights to optimize the car's performance.

2.1.1.2 Project Working

The neural network is trained using the NEAT algorithm. The NEAT algorithm is a genetic algorithm that evolves over time from a basic neural network to a more advanced and complex one depending on the fitness function by going further and further.

Inputs: The main information the car will use to drive is the distance to the walls in front and next to it. The car has five sensors:

- In front
- Two in the diagonals
- Two on each side

The sensors are represented by a green line in the rendering. Red means the sensor is detecting a wall.

Outputs: The car has four possible actions:

- Turn left
- Turn right
- Accelerate
- Brake

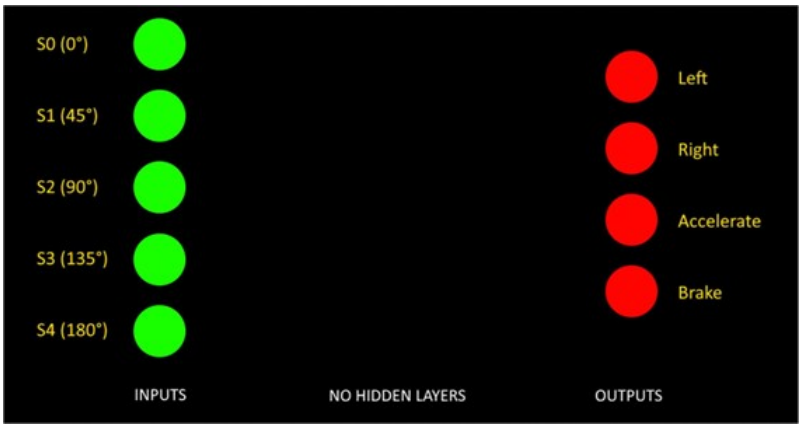

FIGURE 2.1: Representation of Neural Network

Note that we have a minimum speed to respect so that the car doesn't stop completely nor drives too slowly.

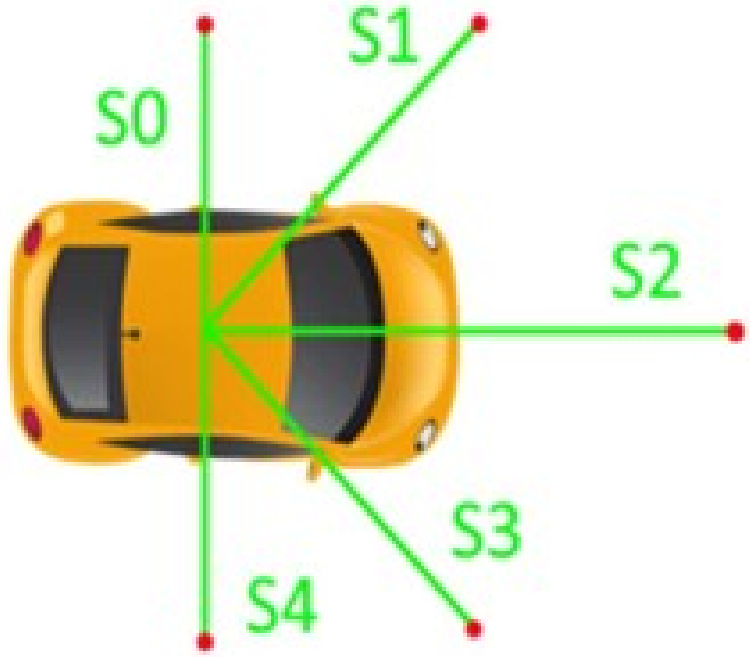

FIGURE 2.2: Representation model of Car in 2D

Fitness: The fitness is calculated by the distance the car has driven. The car is therefore penalized if it crashes.

2.1.1.3 Libraries Used

FIGURE 2.3: Pygame

Pygame: Pygame is a popular open-source library in Python used for creating video games and multimedia applications. It provides functionalities like handling graphics, sounds, and input devices efficiently.

NEAT-Python: NEAT-Python is a Python implementation of the NEAT algorithm. NEAT evolves artificial neural networks (ANNs) by optimizing both their structure and weights over time.

FIGURE 2.4: NumPy

NumPy: NumPy is a powerful library for numerical computing in Python, supporting large multi-dimensional arrays and various mathematical functions.

2.1.1.4 Dynamic Road Maps

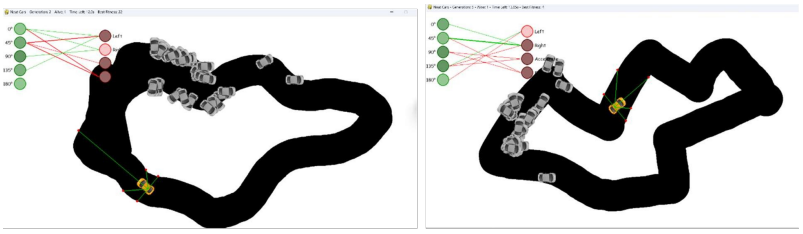

FIGURE 2.5: Dynamic Road Maps

Dynamic Roadmaps refer to real-time, adaptive mapping systems used in autonomous vehicles to navigate through constantly changing environments.

2.1.2 Implementation of Project in 3D

2.1.2.1 Overview of the Project

The DAVE-2 system refers to a self-driving car architecture developed by Stanford University as part of their autonomous driving research.

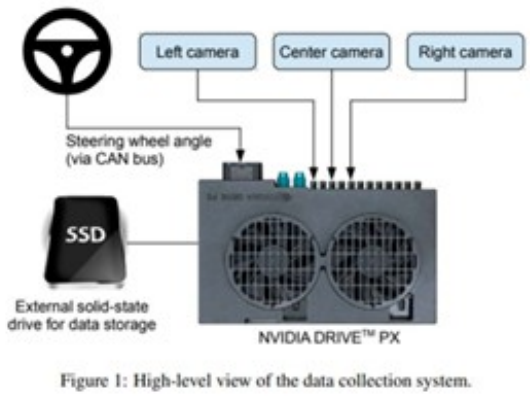

FIGURE 2.6: High-level view of the data collection system

Key Features of DAVE-2:

- **End-to-End Learning:** Uses deep learning to map raw input images to steering commands.
- **Deep Convolutional Neural Network (CNN):** Trained on a dataset of video footage and steering actions.
- **Multiple Camera Input:** Uses left, center, and right cameras for a broader field of view.

2.1.2.2 Training Process

DAVE-2 was trained using supervised learning, where a human driver's actions were used as training labels.

2.1.2.3 Proposed System

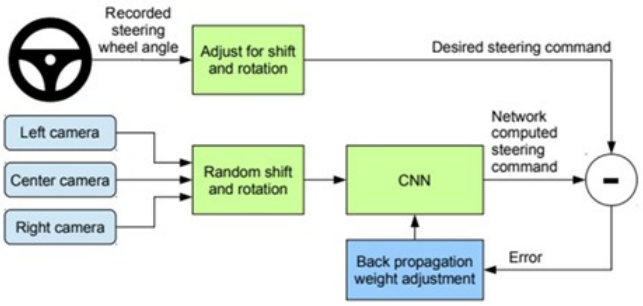

FIGURE 2.7: Proposed System

2.1.3 Simulation Download & Data Collection

2.1.3.1 Udacity Self-Driving Simulator

FIGURE 2.8: Udacity Simulator

2.1.3.2 Data Collection Process

The recorded data is saved in a CSV file containing:

- Center camera images
- Left and right camera images
- Steering angle, throttle, reverse, and speed data

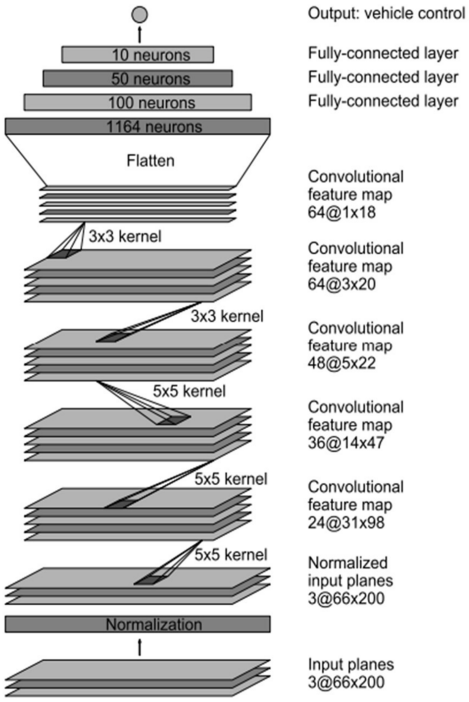

FIGURE 2.13: CNN Architecture

2.1.8 Model Training

- Uses ‘model.fit‘ with batch processing.
- Training runs for 10 epochs with 300 steps per epoch.
- Validation is done with 200 steps.
- Shuffling prevents overfitting.

This methodology ensures a well-structured approach to developing an AI-driven self-driving car simulation using NEAT and deep learning.

Chapter 3

Performance Analysis

3.1 Model Training Performance

In the model training phase, the performance of the model was evaluated by monitoring both the training loss and validation loss over a set number of epochs. By plotting these metrics, we gain insights into how effectively the model learns from the data and generalizes to unseen data.

The code used generates a line plot where the training loss and validation loss are displayed over each epoch. Specifically:

- **Loss Evaluation:** The model's `history.history['loss']` and `history.history['val_loss']` values are plotted to observe trends over time. This allows us to visually assess the model's convergence and stability.
- **Graph Interpretation:** In the plot, if the training loss decreases consistently while the validation loss also decreases or stabilizes, it indicates that the model is learning effectively without overfitting. However, if the validation loss starts to increase as the training loss decreases, it may signal overfitting, suggesting the model is learning too specifically to the training data.
- **Analysis Outcome:** This approach helps identify if more epochs, adjustments in learning rate, or additional regularization techniques are needed.

Overall, tracking these loss values over epochs is essential for evaluating model performance, guiding improvements, and fine-tuning to optimize results on unseen data.

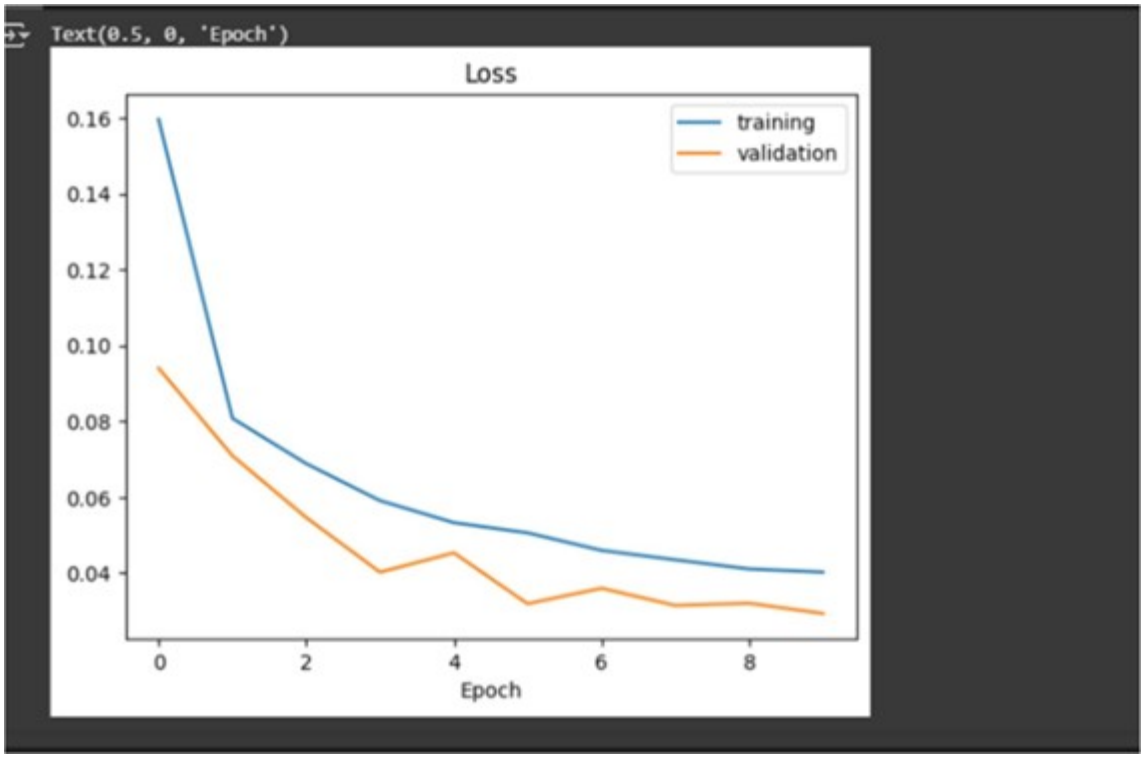

FIGURE 3.1: Performance Analysis Graph

Chapter 4

Results and Discussion

4.1 Implementation of the Neat Cars Project

The implementation of the Neat Cars project represents a significant achievement in building a self-learning autonomous driving agent through the use of NEAT (NeuroEvolution of Augmenting Topologies). The results obtained demonstrate the effectiveness of using evolutionary algorithms to optimize neural networks for driving tasks, leading to the successful creation of an intelligent agent that adapts and improves its driving capabilities over time. This section discusses the key outcomes of the project, including the performance of the driving agent, improvements through generations, and the overall effectiveness of the approach.

4.2 Performance of the Driving Agent

The Neat Cars system shows impressive progress in driving through a track autonomously. During the initial generations, the cars demonstrate limited driving abilities, often crashing or straying off course quickly. However, as the evolutionary process unfolds, the agents begin to display improved driving skills. Through successive generations, the driving agent adapts to its environment, learns to navigate the track, and gradually reduces the frequency of crashes, eventually completing the track without major errors.

The evolutionary process behind the NEAT algorithm, which involves both mutation and crossover, allows for continuous refinement of the neural networks controlling the cars. The key performance indicator for this project is the distance traveled by the car without crashing, and over several generations, this distance increases significantly, indicating the car's growing proficiency.

4.3 Security Measures

Although the Neat Cars project does not directly involve a web-based application, security measures are important when deploying machine learning models in real-world scenarios. Future iterations of the project, particularly if deployed on a cloud platform or integrated into an interactive simulation, should prioritize security to protect the integrity of the models and ensure safe interaction with external users or environments.

Key security considerations include protecting the models from adversarial attacks and ensuring that user inputs do not manipulate the system's behavior. To address these concerns, it would be essential to implement secure APIs that control access to the neural network models. In addition, regular audits of the model's predictions should be conducted to identify any biases or vulnerabilities in the decision-making process. Encryption of any stored data related to the model's evolution and training history could also be considered for privacy and security.

4.4 Data Protection

In autonomous driving projects, ensuring data protection is crucial due to the potential risks of misbehavior from the model. For instance, improper handling of inputs from the environment could cause the car to take unsafe actions, potentially leading to crashes or unsafe driving behavior. Though the Neat Cars project does not handle sensitive user data, the simulation system should be designed to securely handle and store any data generated during the training process.

Future improvements in the project could include logging and storing the training data and the performance metrics securely. Additionally, any data used to assess the car's driving skills (such as sensor inputs and fitness scores) should be stored in a manner that protects the integrity of the system, preventing unauthorized users or external systems from tampering with the data.

4.5 User Efficiency

The Neat Cars project focuses on automating the driving process using machine learning, so user efficiency is not a direct concern in this context. However, the project can still benefit from an easy-to-understand interface for monitoring the progress of the agent.

In future implementations or expansions of this project, user efficiency could be enhanced by providing real-time visualization of the car's performance and offering controls that allow users to intervene or alter parameters, such as the track layout or the neural network architecture.

Providing a clear dashboard with metrics such as the current generation number, car's fitness score, and distance traveled without crashing can allow users or developers to better assess the training progress and make adjustments accordingly. The interface can also be optimized to show real-time simulation updates, providing users with a better understanding of the evolutionary process and how neural network changes affect driving performance.

4.6 Continuous Improvement

The NEAT algorithm ensures that the Neat Cars system benefits from continuous improvement. With each generation, the genetic algorithm selects and breeds the best-performing networks, allowing the driving agent to evolve and become more capable. As the model progresses through successive generations, new topologies are added, and the neural networks grow more complex, leading to enhanced driving behaviors.

The data-driven approach enables the model to adapt over time, learning new strategies to handle obstacles, turns, and other challenges encountered on the track. This continuous evolution of the neural network makes the system more robust and able to handle a variety of driving scenarios. It is anticipated that further training and fine-tuning of the model will continue to improve its performance, allowing the agent to drive even more effectively.

Chapter 5

Conclusion and Future Scope

5.1 Conclusion

The development of a self-driving car system that integrates both 2D and 3D methodologies has achieved significant milestones in autonomous navigation. In 2D settings, the system excelled at lane detection, road sign recognition, and basic path following, delivering efficient and accurate performance on straightforward paths.

In more complex environments, 3D integration, incorporating LIDAR and 3D perception models, enabled advanced obstacle detection and dynamic navigation. Path planning and control were effective overall, though challenges remain in unpredictable or cluttered scenarios, such as construction zones or adverse weather conditions.

This project demonstrates that combining 2D and 3D technologies offers a robust solution for autonomous vehicles across varied conditions.

5.2 Future Scope

1. **Enhanced Sensor Fusion:** Future work will improve the fusion of 2D and 3D data, focusing on reliability in adverse weather by refining the combination

of camera, LIDAR, and radar inputs.

2. **Advanced Path Planning:** Incorporating algorithms like Deep Reinforcement Learning (DRL) could enhance decision-making in complex environments, enabling faster, more accurate responses to dynamic obstacles and traffic changes.

3. **Real-Time Data Processing:** Optimizing algorithms to reduce latency will allow more effective handling of sudden changes, such as lane shifts and pedestrian crossings.

4. **Expanded Testing:** Additional real-world testing in suburban, highway, and off-road environments will assess the system's adaptability and robustness.

5. **Improved AI Models:** Using advanced machine learning models like CNNs and RNNs could boost object recognition, enhancing the system's ability to handle complex and ambiguous situations.

These enhancements will evolve the self-driving system into a more efficient, reliable, and intelligent solution for autonomous transportation.
